History of the Numerical Methods of Pi

By Andy Yopp
MAT3010 Spring 2003
Appalachian State University

This project is composed of a worksheet, a time line, and a reference sheet. This material is intended for an audience consisting of undergraduate college students with a background and interest in the subject of numerical methods. This material is also largely recreational. Although there probably aren't any practical applications for computing pi in an undergraduate curriculum, that is precisely why this material aims to interest the student to pursue their own studies of mathematics and computing.

The time line is a compilation of several other time lines of pi. It is explained at the bottom of the time line and further on the worksheet reference page. The worksheet is a take-home assignment. It requires that the student know how to construct a hexagon within and without a circle, use iterative algorithms, and code in C. Therefore, they will need a variety of materials and a significant amount of time.

The most interesting part of the project was just how well the numerical methods of pi have evolved. Currently, there are iterative algorithms available that are more precise than a graphing calculator with only a single iteration of the algorithm. This is a far cry from the rough estimate of 3 used by the early Babylonians. It is also a different entity altogether than what the circle-squarers have devised. The history of pi and its numerical methods go hand-in-hand through shameful trickery and glorious achievements. It is through the evolution of these methods which I will try to inspire students to begin their own research.
A $\pi$ Timeline

- c. 2000 B.C.E. Babylonians use $\pi = \frac{31}{8} = 3.125$
  Egyptians use $\pi = \frac{256}{81} = 3.1605$

- c. 1100 B.C.E. Chinese use $\pi = 3$

- c. 550 B.C.E. Bible, I Kings 7:23 implies $\pi = 3$

- c. 440 B.C.E. Hippocrates of Chios squares the lune

- c. 434 B.C.E. Anaxagoras attempts to square the circle

- c. 430 B.C.E. Antiphon and Bryson articulate the principle of exhaustion

- c. 420 B.C.E. Hippias discovers the quadratix

- c. 335 B.C.E. Dinostratos uses the quadratix to "square the circle"

- c. 240 B.C.E. Archimedes uses a 96-sided polygon to establish $\frac{223}{71} < \pi < \frac{22}{7}$
  He also uses a spiral to "square the circle."

- 2nd cent. C.E. Claudius Ptolemy uses $\pi = 3^\circ 8' 30'' = \frac{377}{120} = 3.1466...$

- 3rd cent. C.E. Wang Fau uses $\pi = \frac{142}{45} = 3.155...$
  Chung Hing uses $\pi = \sqrt{10} = 3.166...$
263 C.E. Liu Hui uses \( \pi = \frac{157}{50} = 3.14 \)

---

c. 450 Tsu Ch'ung-chih finds \( \pi = \frac{355}{133} \) by using a circle 10 feet across

---

c. 530 Aryabhata uses \( \pi = \frac{62,832}{20,000} = 3.1416 \)

---

c. 650 Brahmagupta uses \( \pi = \sqrt{10} = 3.166\ldots \)

---

1220 Leonardo de Pisa (Fibonacci) finds \( \pi = 3.141818\ldots \)

---

1429 Al-Kashi calculates \( \pi \) to 16 decimal places

---

1573 Valentinus Otho finds \( \pi = \frac{355}{113} = 3.1415929 \)

---

1593 Francois Viete expresses \( \pi \) as an infinite product using only 2s and \( \sqrt{2s} \); Adrien Romanus finds \( \pi \) to 15 places

---

1596 Ludolph van Ceulen calculates \( \pi \) to 35 places

---

1621 Willebrod Snell refines Archimedes method

---

1630 Grienberger uses Snell's refinement to calculate \( \pi \) to 39 decimal places

---

1654 Huygens proves the validity of Snell's method

---

1655 John Wallis finds an infinite rational product for \( \pi \); Brounker converts it to a continued fraction

1999  Kanada calculates over 206 billion digits using the Gauss-Legendre algorithm

What's Next???

This time line was compiled from three different sources that were all very similar, yet differed in small aspects. They were: The Joy of Pi, A History of Pi, and A Piece of Pi. Please refer to the worksheet resource page for more information on these books.
**Introduction to the Numerical Methods of pi**

**Worksheet**

This worksheet will introduce you to some of the ways in which people calculate $\pi$. Currently, people can calculate $\pi$ correctly to more than 50 billion digits using computers. Why do they do it? Well, it’s hard to explain, but understanding and calculating this mysterious number has captivated people for more than 2000 years. With this much time devoted to the problem, many methods have emerged. Very often those methods have matured and lent insights to better ones as time went on. Therefore, to better understand the methods that we use today, let’s look at how it was done in the past. Have the $\pi$ time line, some paper, a calculator, and a compass handy. Later, be ready to write a small program.

1. Briefly study the $\pi$ time line.

2. History's first scientific attempt to compute $\pi$ was done by Archimedes of Syracuse in about 240 B.C.E. Recall the upper and lower bounds which he found for $\pi$. On a blank piece of paper, draw a circle and construct a hexagon inside of it. Next, draw the radii of the circle to two adjacent vertices of the hexagon, forming an equilateral triangle with one side of the hexagon. Find the perimeter of the hexagon ________ and the circumference of the circle ________. Write an inequality that describes the numbers you just found ________ > ________ and solve for $\pi$ _________. Next, draw a circumscribed hexagon about the circle. In the new hexagon, construct an equilateral triangle as before. If $r$ is the side of the triangle formed by the radius, and $h$ is the shortest side, $r^3 = 3h$. Solve for $h$ ________. Now find the perimeter of the new hexagon ________. Substitute the value of $h$ to get a formula for the perimeter in terms of $r$ ________. Write an inequality expressing the relationship between the circumference of the circle and the perimeter of the circumscribed hexagon ________ < ________ and solve for $\pi$ _________. Now combine both of your inequalities ________ < ________.

Compare these to Archimedes' upper and lower bounds. He used 96-gons! Could you code this?

3. Aryabhata was a prominent Indian mathematician. He used the following method for finding $\pi$ between 500 and 1000 C.E.:

"Add 4 to 100, multiply by 8, and add again 62,000. The result is approximate value of the circumference when the diameter is twenty thousand."

Decipher the statement and write it as a formula _________.

Use the formula you just wrote to estimate $\pi$. What do you get? ________.
4. In 1655, John Wallis discovered an infinite product that equaled $\pi$:

$$\frac{\pi}{2} = \frac{(2 \times 2 \times 4 \times 4 \times 6 \times 6 \times 8 \ldots)}{(1 \times 3 \times 3 \times 5 \times 5 \times 7 \times 7 \ldots)}$$

This was revolutionary because the irrational number $\pi$ could be expressed as products of the even and odd integers! Try calculating a few terms of this product ________. Why or why wouldn't you want to use this on a computer? ____________________________________________________________________________.

5. Recall from the time line that James Gregory and Gottfried Leibniz independently discovered the following infinite series:

$$\arctan(x) = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \frac{x^9}{9} - \frac{x^{11}}{11} \ldots$$

The trigonometric argument behind this formula relies on the fact that the tangent of 45 degrees is one. 45 degrees equals $\frac{\pi}{4}$ in radians, therefore, if you take the arctangent of one, you get $\frac{\pi}{4}$ radians. Using a calculator, try arctan(1) using the above formula ________. Add 6 more terms onto the formula to get another approximation ________. How many accurate digits do you have? ________. Why or why wouldn't you use this algorithm to approximate $\pi$ using a computer? Can you guess how fast it would converge? ____________________________________________________________________________.

From the beginning of the 18\textsuperscript{th} century, $\pi$ was calculated using John Machin's formula:

$$\frac{\pi}{4} = \arctan\left(\frac{1}{5}\right) - \arctan\left(\frac{1}{239}\right).$$

This formula was a lot more powerful than the Gregory-Leibniz series because it converged much faster. Extensions to Machin's formula have been used on supercomputers to calculate $\pi$ to more than one million places. Since then, even more powerful formulas have been devised. Now we will introduce some modern methods.

6. In 1914, Indian mathematician Srinivasa Ramanujan found this formula:
Try plugging $n = 0$ into your calculator and write down the result ____________.

Keep in mind that we haven't even reached the computer age yet!

7. In the 1990's the Chudnovsky Brothers developed this formula:

$$\frac{1}{\pi} = \frac{4n!}{9801 \sum_{n=0}^{\infty} \left( \frac{(n!)^4}{(4 \times 99)^{4n}} \right)} \times [1103 + 26390n]$$

Try plugging $n = 0$ into your calculator and write down the result ____________.

Again, plug $n = 0$ into your calculator and write down the result ____________.

Are you surprised?

8. On September 18, 1999, Yasumasa Kanada used the Gauss-Legendre method which uses the arithmetic geometric mean to calculate $\pi$ to more than eight billion digits on one of the world's most powerful computers! Here is the algorithm:

$$a_0 = 1; b_0 = \frac{\sqrt{2}}{2}; t_0 = \frac{1}{4}; x_0 = 1$$

$$a_{(n+1)} = \frac{(a_n + b_n)}{2} \quad b_{(n+1)} = \sqrt{(a_n b_n)}$$

$$t_{(n+1)} = t_n - x_n \left( a_{(n+1)} - a_n \right)^2 \quad x_{(n+1)} = 2x_n$$

$$\lim_{n \to \infty} \left( \frac{a_n + b_n}{4t_n} \right) = \pi$$

Write a C program that performs this algorithm. Run it, and comment on how fast it converges ____________________________________________________

__________________________________________________________________.

How many iterations did it take to converge?______________________________.

9. On your own, find 3 formulas or algorithms that have not been listed on this worksheet. Code them in C, and comment on their performance.
So how do you like $\pi$? Maybe by now you can get a feel for why so many people are endlessly calculating this mysterious number. Actually, the reason that most people study $\pi$ is because they are looking for patterns and order in the seemingly random digits. $\pi$ is a fundamental building block of the universe. You could say that those who study $\pi$ are trying to "read between the lines" of the very fabric of the universe, and as we can see from the time line, this search has been going on for a very long time. Although no relevant patterns have been found in $\pi$ and it has not yet been proven that its digits are random, here are some interesting facts that might help to accelerate your own studies of $\pi$!

Hint for number 5: In order to calculate 100 digits of $\pi$ using the Gregory-Leibniz series, you would have to calculate more terms than there are particles in the universe!

Since there are 360 degrees in a circle, look at the 360\textsuperscript{th} digit of $\pi$ – the number 360 is centered over that digit!

The sequence 3333333 appears at the 710,100\textsuperscript{th} digit and again at the 3,204,765\textsuperscript{th} digit.

The sequence 0123456789 occurs in the decimal expansion of $\pi$ six times in the first 50 billion digits; the sequence 9876543210 occurs five times, and the sequence 27182818284 ($e$) occurs at the 45,111,908,393\textsuperscript{rd} decimal place!
Resource List

The Joy of Pi is an amazing book that is aimed at more of a leisurely audience. It contains facts about pi and its history, its calculation, trivia, and those who have participated in its history.

This article originated as a Master's Thesis by Herman Harris Jr. at Kansas State Teacher's College. It is about 35 pages long.

This is one of the most thorough and in-depth books out there on pi. It is one of the most frequently referenced books that you will see in other studies on the history of pi. This book delves into the rich history of the number and those who worked on it tirelessly. Additionally, it contains much of the math that goes along with that history. Note, there are updated editions of this book.

This is a wonderful activity book for teachers. It is aimed at grades 6-8, but I found a lot of useful material in it. It is seems to be a conglomeration of material from The Joy of Pi and A History of Pi, so in some ways it was difficult to differentiate information, and occasionally there was information like dates that did not agree. But still, its a unique and useful book.
